SUPERSWAPPING

Abstract. Supertask theory is used here to prove a contradictory result which involves the consistency of ω-order and the Axiom of Infinity.

As is well known, supertask theory assumes the possibility of performing infinitely many actions in a finite time (see [3] for background details). The short discussion that follows analyzes this assumption by mean of an elementary supertask which consist in interchanging infinitely many times one of the rows of an ω-ordered table. In fact, consider the ω-ordered table $\mathcal{N}$[1] of all natural numbers whose successive rows are 1, 2, 3, …; and a supertask $\langle c_i \rangle_{i \in \mathbb{N}}$ each of whose successive actions c_i consist in interchanging the relative positions of the i-th and $(i+1)$-th rows of $\mathcal{N}$. As a consequence of those successive interchanges, number 1, originally placed in the first row, will be successively placed in the 2nd, 3rd, 4th ... row of $\mathcal{N}$.

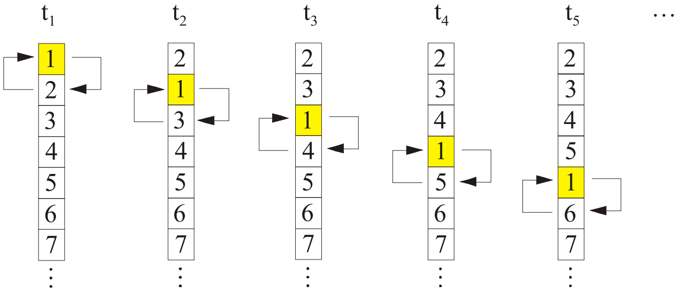

Figure 1: Superswapping in the ω-ordered table of natural numbers.

Let $\langle t_i \rangle_{i \in \mathbb{N}}$ be an ω-ordered sequence of instants within the real interval $[t_a, t_b]$ whose limit is t_b, and assume the successive interchanges c_i of supertask $\langle c_i \rangle_{i \in \mathbb{N}}$ are performed at the successive instants t_i of $\langle t_i \rangle_{i \in \mathbb{N}}$. Since t_b is the limit of $\langle t_i \rangle_{i \in \mathbb{N}}$, at t_b supertask $\langle c_i \rangle_{i \in \mathbb{N}}$ will have been completed. The one to one correspondence $f(t_i) = r_{i+1}$ between $\langle t_i \rangle_{i \in \mathbb{N}}$ and the set of rows $\langle r_i \rangle_{i \in \mathbb{N},\, i>1}$ of table $\mathcal{N}$ proves that at t_b the row corresponding to number 1 has been interchanged with each of the infinitely many rows of $\mathcal{N}$. Therefore, at t_b each natural number $n, (n > 1)$ will be placed in the $(n-1)$-th row of $\mathcal{N}$. But in which row will be placed number 1 at t_b? It cannot be in the n-th row because in that row is now number $n+1$. In addition, if it were positioned in the n-th row then only a finite number $n-1$ of interchanges would have been performed. We must conclude therefore that at t_b number 1 has disappeared from the table. An this in spite that none of the countably many performed interchanges c_1, c_2, c_3, … has made it disappear. Some infinitists claim this way of reasoning is fallacious because, although no interchange c_i makes number 1 disappear from the table, the completion of all of them does it. As if the completion of the ω-ordered sequence[2] of interchanges $\langle c_i \rangle_{i \in \mathbb{N}}$, as such completion, where a subsequent additional action c_ω different from all c_i previously performed, and taking place just at[3] $t \geq t_b$. We will now discus this picturesque pretension. For this, consider the ω-ordered sequence $\langle e_i \rangle_{i \in \mathbb{N}}$ of effects caused by the ω-ordered sequence of interchanges $\langle c_i \rangle_{i \in \mathbb{N}}$ of our supertask, each interchange c_i causing the effect e_i (the interchange of the i-th and the (i+1)-th rows). We have proved this ω-ordered sequence of interchanges $\langle c_i \rangle_{i \in \mathbb{N}}$ has the final effect of removing number 1 from the table. Let e_ω be this final effect. According to the definition of supertask $\langle c_i \rangle_{i \in \mathbb{N}}$, each interchange c_i causes the effect e_i; in consequence, the one to one correspondence between $\langle c_i \rangle_{i \in \mathbb{N}}$ and $\langle e_i \rangle_{i \in \mathbb{N}}$ defined by $f(c_i) = e_i$ proves that in fact no interchange c_i causes e_ω. There must therefore exist an additional subsequent action c_ω (the completion of all previous $\langle c_i \rangle_{i \in \mathbb{N}}$ as such completion, according to some infinitists) causing e_ω. In conclusion we need an $(\omega+1)$-ordered sequence of actions to explain why number 1 disappear from the table at t_b after performing supertask $\langle c_i \rangle_{i \in \mathbb{N}}$. But we have just proved it disappear as a consequence of an ω-ordered (not $(\omega+1)$-ordered) sequence of actions, the sequence of interchanges $\langle c_i \rangle_{i \in \mathbb{N}}$. Even if that *ad hoc* additional cause c_w (the completion of $\langle c_i \rangle_{i \in \mathbb{N}}$ as such completion) were inevitable we could always analyze the first ω-ordered sequence of interchanges $\langle c_i \rangle_{i \in \mathbb{N}}$ and then the last c_ω causing the effect e_ω. We will find, as we have just proved, that the ω-ordered sequence suffices to make number 1 disappear: once performed the successive interchanges c_1, c_2, c_3, …, *and only them*, number 1 is no longer in the table, in spite that none of the countably many performed interchanges c_1, c_2, c_3, … removed it from the table.

---

[1] As usual, I will use symbol $\mathbb{N}$ to denote the set of natural numbers and, for the sake of clarity, symbol $\mathcal{N}$ to denote the ω-ordered table of all of them.

---

[2] An ω-ordered sequence is one which is both complete (as the actual infinity requires) and uncompletable (because no last action completes it). To be complete and uncompletable does not seem to be a confortable logical status.

[3] At any instant prior to t_b, whatsoever it be, there will still remain infinitely many actions to be performed while only a finite number of them will have been performed. This unaesthetic and huge asymmetry is invariably forgotten in infinitist literature.

There exist an inevitable asymmetry between the ω-ordered sequence of performed actions $\langle c_i \rangle_{i \in \mathbb{N}}$ and the $(\omega + 1)$-ordered sequence of resulting effects $\langle \langle e_i \rangle_{i \in \mathbb{N}}, e_\omega \rangle$. This asymmetry is a consequence of assuming that it is possible to end up an endless sequence of actions[4]: once ended, we will always have an unexplainable last state caused by a nonexistent last action. This asymmetry forces infinitists to claim the completion of the ω-ordered sequence of actions is the required last action causing the final effect e_ω. Any other way of reasoning is fallacious, they claim. But it is quite clear where the fallacy is. We have just proved the ω-ordered sequence of interchanges $c_1, c_2, c_3, \dots,$ *and only them*, removes and does not remove number 1 from table $\mathcal{N}$. According to Aristotle this contradiction raises from assuming the possibility to traverse the untraversable [1, page 291]. As is well known, and Cantor himself proved [2, pages 110-118], ω-order, the untraversable, is a consequence of assuming the existence of complete infinite totalities, the Axiom of Infinity in modern terms. Is therefore that axiom the ultimate cause of the above contradiction.

Things are radically different from a finitist perspective -from the potential infinity perspective. In fact, from this perspective only finite totalities can be considered as completed totalities. And in any finite version of the above superwapping, number 1 always ends in the last row of the table as a consequence of a last interchange placing it there. In other terms any finite sequence of n successive swappings $\langle c_i \rangle_{1 \leq i \leq n, \forall n \in \mathbb{N}}$ is consistent, only the ω-ordered sequence $\langle c_i \rangle_{i \in \mathbb{N}}$, i.e. the completion of an uncompletable sequence of actions, is inconsistent.

[4] And not only of assuming that possibility, infinitists also pretend to explain the way it is accomplished: by pairing off two endless sequences, the one of actions the other of instants at which the successive actions are performed. Thus, in order to end up an endless sequence of actions all we have to do is to pair the endless sequence of actions with the endless sequence of instants at which they are performed, as if by pairing off two impossibilities a possibility result.
